Day 1: Introduction to Data Science

Kenneth Benoit and Slava Mikhaylov

Introduction to Data Science and Big Data Analytics

17 August 2015

Day 1 Outline

- Logistics and introductions
- Defining Data Science
- ► The R statistical package
- Data structures
- Further course preview
- Preview of lab sessions

Pitch of this course

- Whom this class is for
 - (typically) graduate-level applied researchers with some prior experience in quantitative methods
 - those requiring the fundamentals of data science
 - people working with typically large datasets and databases
 - those seeking a practical introduction to data analysis using R
- Prerequisites
 - ▶ at least one prior course in quantitative methods or statistics
 - ▶ familiarity, or willingness to learn, R
 - ability to use a text editor and spreadsheet is helpful
 - (optional) ability to process data files in a programming language such as Python

Learning objectives

- an overview of data science and the challenges of working with big data
- learning the R statistical package and practical methods for manipulating and analyzing data
- formulating research questions using data analytics
- how to acquire, process, store, and use data, both structured and unstructured
- the basics of statistical inference including probability and probability distributions, modelling, experimental design

Learning objectives (cont.)

- an overview of classification methods and methods for assessing model fit
- supervised learning approaches, including linear and logistic regression, decision trees, and naive Bayes
- unsupervised learning approaches, including clustering, association rules, and principal components analysis
- quantitative methods of text analysis, including mining social media and other online resources

Who we are

- ▶ In the lectures:
 - Ken Benoit, London School of Economics kbenoit@lse.ac.uk
 - Slava Mikhaylov, University College London s.mikhaylov@ucl.ac.uk
- ▶ In the labs:
 - Paul Nulty, p.nulty@lse.ac.uk
- ► Course homepage: http://github.com/kbenoit/ME114

Class schedule: Typical day

- 10:00–11:15 Lecture part 1 (NAB Thai Theatre)
- 11:25–12:45 Lecture part 2 (NAB Thai Theatre)
- 14:00–15:30 Lab Group 1 (TW2.4.02)
- 15:30–17:00 Lab Group 2 (TW2.4.02)

Essential course resources

On-line course resources GitHub repository http://github.com/kbenoit/ME114 Moodle page https://shortcourses.lse.ac.uk/course/ view.php?id=158

- Using GitHub and forking the course repo
- RStudio and GitHub integration
- ▶ How to complete (and submit) assignments
 - ► For a brief on-line introduction to RMarkdown, which we will use for completing the exercises for the course, see https://goo.gl/ZqOwUe

Course reading materials

- The R statistical package resources on https://cran.r-project.org/doc/manuals
- Key readings
 - ▶ James et al. (2013) An Introduction to Statistical Learning: With applications in R. Springer.
 - ► Zumel, N. and Mount, J. (2014). *Practical Data Science with R.* Manning Publications.
- Additional readings recommended but we understand that this course will be intensive

What is "data science"?

- extraction or generation of knowledge from data
- extends "data mining", using computational and algorithmic methods
- combines applied statistical methods with advances in computer science, especially machine learning
- may involve "unstructured" data, especially text, but also video and images
- closely tied to computational methods

Why focus on data types and structures?

- "data" mining and "data" science imply that we know how to work with data
- data structures are not neutral they shape how we record, see, and have the ability to analyze information
- much of the actual work in data mining and data analysis is done at the data "mungeing" stage

Basic (atomic) data types in R

numeric 8-byte numeric representations integer non-floating point numbers character text logical TRUE or FALSE

Recursive types also exist, such as lists and vectors; there are also special classifications for ${\tt NA}$

Basic data types in R: integer

```
x <- 10
typeof(x)
## [1] "double"
is.integer(x)
## [1] FALSE
x <- 7L # force integer type
typeof(x)
## [1] "integer"
object.size(x)
## 48 bytes
as.integer(3.14)
## [1] 3
```

Basic data types in R: character

```
typeof("test string")
## [1] "character"
object.size("a")
## 96 bytes
s <- ""
                 # Unicode
cat(s)
##
as.character("3.14") # coerce numerics to character
## [1] "3.14"
```

Basic data types in R: numeric

```
x <- 10.5  # assign a numeric value
x  # print the value of x

## [1] 10.5

typeof(x)  # print the class name of x

## [1] "double"

object.size(x)  # show storage size in bytes

## 48 bytes</pre>
```

is.*() and as.*()

```
is.numeric(x) # is the object of numeric type?
## [1] TRUE
is.numeric(7.1)
## [1] TRUE
is.numeric("7.1")
## [1] FALSE
is.numeric(as.numeric("7.1"))
## [1] TRUE
```

Basic data types in R: logical

A logical value is 'TRUE' or 'FALSE', often created via comparison between variables.

```
1 < 2
              # is 1 less 2
## [1] TRUE
x \leftarrow c(1, 2, 3)
y \leftarrow c(4, 3, 2)
      # vectorized comparison
x > y
## [1] FALSE FALSE TRUE
typeof(x > y)
## [1] "logical"
```

Difference between 'mode' and 'class'

- 'atomic' modes are numeric, complex, character and logical
- recursive objects have modes such as 'list' or 'function' or a few others
- an object has one and only one mode
- 'class' is a property assigned to an object that determines how generic functions operate with it - not a mutually exclusive classification
- an object has no specific class assigned to it, such as a simple numeric vector, it's class is usually the same as its mode, by convention
- an object's mode can be changed through coercion, without necessarily changing the class

Numerical precision issues

- floating point numbers are approximations of numbers
 - precision: anything more than 16 base-10 digits must be approximated
 - fractions: approximated if not $\frac{x}{2^k}$
 - ▶ anything over stated precision is truncated: 3.57e21 + 1 = 3.57e21

```
1 - 4/5 - 1/5 # not zero!
## [1] -5.551115e-17
```

Machine limits

```
.Machine$integer.max
## [1] 2147483647
.Machine[c("double.xmin", "double.xmax", "double.digits")]
## $double.xmin
## [1] 2.225074e-308
##
## $double.xmax
## [1] 1.797693e+308
##
## $double.digits
## [1] 53
```

Alternatives (Stata)

- single and double precision: http://blog.stata.com/2012/04/02/ the-penultimate-guide-to-precision/
- ▶ R has only double precision

Common input formats

- CSV
- Excel
- "fixed formats"
- relational databases
- embedded tags: Extensible Markup Language (XML)
- key-value pair schemes (JSON)
 - examples of JSON and XML: http://json.org/example

Special issue: text encoding

- ► a "character set" is a list of character with associated numerical representations
- ► ASCII: the original character set, uses just 7 bits (2⁷) see http://ergoemacs.org/emacs/unicode_basics.html
- ► ASCII was later extended, e.g. ISO-8859 http://www.ic.unicamp.br/~stolfi/EXPORT/www/ ISO-8859-1-Encoding.html, using 8 bits (2⁸)
- but this became a jungle, with no standards: http://en.wikipedia.org/wiki/Character_encoding

Solution: Unicode

- Unicode was developed to provide a unique number (a "code point") to every known character – even some that are "unknown"
- problem: there are more far code points than fit into 8-bit encodings. Hence there are multiple ways to encode the Unicode code points
- variable-byte encodings use multiple bytes as needed. Advantage is efficiency, since most ASCII and simple extended character sets can use just one byte, and these were set in the Unicode standard to their ASCII and ISO-8859 equivalents
- ▶ two most common are UTF-8 and UTF-16, using 8 and 16 bits respectively

Warnings with text encodings

- Input texts can be very different
- ► Many text production software (e.g. MS Office-based products) still tend to use proprietary formats, such as Windows-1252
- Windows tends to use UTF-16, while Mac and other Unix-based platforms use UTF-8
- ► Your eyes can be deceiving: a client may display gibberish but the encoding might still be as intended
- No easy method of detecting encodings (except in HTML meta-data)

What is a "Dataset"?

- ► A dataset is a "rectangular" formatted table of data in which all the values of the same variable must be in a single column
- ► Many of the datasets we use have been artificially reshaped in order to fulfill this criterion of rectangularity

Revisting basic data concepts

- ▶ The difference between tables and *datasets*
- ► This is a (partial) dataset:

```
incumbf wonseatf
district
       Carlow Kilkenny Challenger
                                       Lost.
2
       Carlow Kilkenny Challenger
                                       Lost
5
       Carlow Kilkenny Incumbent
                                        Won
100 Donegal South West Challenger
                                      Lost
459
               Wicklow Incumbent
                                        Won
464
               Wicklow Challenger
                                       Lost
```

► This is a table:

Lost Won Challenger 266 60 Incumbent 32 106

► The key with a dataset is that all the values of the same variable must be in a single column

Example: Comparative Manifesto Project dataset

Note: Available from https://manifestoproject.wzb.eu/

```
# load in a subset of the Manifesto Project dataset, with counts
load(url("http://kenbenoit.net/files/cmpdata.Rdata"))
# View(cmpdata)
```

Example: Comparative Manifesto Project dataset

This is "wide" format:

	country ⁼	countryname [‡]	oecdmember [‡]	eumember [‡]	edate +	date	party [‡]	partyname
203	42	Austria	10	10	2008-09-28	200809	42320	SPOE Social Democratic Party
204	42	Austria	10	10	2008-09-28	200809	42110	Green Party
205	42	Austria	10	10	2008-09-28	200809	42520	OVP: People's Party
206	42	Austria	10	10	2008-09-28	200809	42420	FPO: Freedom Party
207	42	Austria	10	10	2008-09-28	200809	42710	BZO Alliance for the Future of Austria
208	42	Austria	10	10	2008-09-28	200809	42220	KP <d6> Communist Party of Austria</d6>
314	21	Belgium	10	10	1991-11-24	199111	21521	CVP Christian People's Party
315	21	Belgium	10	10	1991-11-24	199111	21111	ECOLO Francophone Ecologists
316	21	Belgium	10	10	1991-11-24	199111	21321	SP Flemish Socialist Party
317	21	Belgium	10	10	1991-11-24	199111	21522	PSC Christian Social Party
318	21	Belgium	10	10	1991-11-24	199111	21421	PVV Party of Liberty and Progress
319	21	Belgium	10	10	1991-11-24	199111	21913	VU People's Union
320	21	Belgium	10	10	1991-11-24	199111	21912	FDF Francophone Democratic Front

Long v. wide formats

- reshape
 - the "old" R way to do this, using 'base::reshape()'
 - problem: confusing and difficult to use
- reshape2
 - from Hadley Wickham's reshape2 package
 - data is first 'melt'ed into long format
 - then 'cast' into desired format

Example: wide to long using reshape2

```
require(reshape2, quietly = TRUE)
# this will select only the "per" variables for measurement
cmpdataLong <- melt(cmpdata,
id.vars = c("countryname", "party", "date"),
measure.vars = names(cmpdata)[21:76],
variable.name = "category",
value.name = "catecount")
# why do this?
cmpdataLong$category <- as.character(cmpdataLong$category)
# View(cmpdataLong)</pre>
```

Example: wide to long using reshape2

```
require(reshape2, quietly = TRUE)
# now we can get summary statistics across countries, e.g. for economic
with(subset(cmpdataLong, grepl("^per7", category)),
    table(countryname, category))
##
               category
  countryname
             per701 per702 per703 per704 per705 per706

```

Relational data bases

- ▶ invented by E. F. Codd at IBM in 1970
- A relational database is a collection of data organized as a set of formally defined tables
- These tables can be accessed or reassembled in many different ways without having to reorganize the underlying tables that organize the data
- RDBMS: a relational database management system.
 Examples include: MySQL, SQLite, PostgreSQL, Oracle. MS
 Access is a lite version of this too.
- ► The standard user and application programmer interface to a relational database is structured query language (SQL)

Example

example: Database of Parties, Elections, and Governments (DPEG) relational database

```
SELECT c.countryName, c.countryAbbrev, p.* FROM party AS p
LEFT JOIN country AS c
ON p.countryID = c.countryID
```

 simpler example: convert CMP data into relational tables for countries, parties, elections, categories, and counts

Basic relational structures

- tables
 - also known as "relations"
 - tables define the forms of the data that are linked to other data through key relations
- keys: how tables are cross-referenced
 - primary key: an column in a table that uniquely identifies the remaining data in the table
 - foreign key: a field in a relational table that matches the primary key column of another table
 - join operations link tables in a structured query

Normal forms 1

"Normalizing" a database means creating a proper set of relations First normal form: No Repeating Elements or Groups of Elements

```
head(select(cmpdata, countryname, partyname, date, per108, per110))
##
      countryname
                                   partyname date per108 per110
## 175
          Austria
                          FP Freedom Party 199010
         Austria
                        GA Green Alternative 199010
## 176
## 177
      Austria SP Social Democratic Party 199010
      Austria
                          VP People's Party 199010
## 178
## 179
      Austria
                           FP Freedom Party 199410
                                                             11
## 180
         Austria
                            LF Liberal Forum 199410
```

Here, this is violated because of the wide format of per108 and per110. To solve this, we have to move this to long format.

Normal forms 2

Second normal form: No Partial Dependencies on a Concatenated Key

```
head(cmpdataLong)
##
    countryname party date category catcount
## 1
        Austria 42420 199010
                              per101
## 2
      Austria 42110 199010
                              per101
## 3
     Austria 42320 199010 per101
## 4
    Austria 42520 199010
                              per101
## 5
    Austria 42420 199410
                              per101
                              per101
## 6
       Austria 42421 199410
```

Here, the format is still violated, because party 42420 is repeated. To solve this we need to create a party table and link to it using a foreign key.

Normal forms 3

Third normal form: No Dependencies on Non-Key Attributes. Every non-prime attribute of data in a table must be dependent on a primary key.

```
head(cmpdataLong)
##
    countryname party date category catcount
## 1
        Austria 42420 199010
                              per101
## 2
        Austria 42110 199010

## 6
```

Here, this is violated because election data repeats across multiple values of the category count table, when it should have its own table.

Non-relational data

- recently popularized because so much data is unstructured, and dealing with new data forms in a classic relational setting requires changing the entire schema
- non-relational systems typically define data using key-value pairs
- example: JSON see http://kenbenoit.net/files/JSONexample.json

Compression: sparse matrix format

used because many forms of matrix are very sparse - for example, document-term matrixes

```
require(quanteda, warn.conflicts = FALSE, quietly = TRUE)
myDfm <- dfm(inaugTexts, verbose = FALSE)</pre>
myDfm[1:10, 1:5]
## Document-feature matrix of: 10 documents. 5 features.
## 10 x 5 sparse Matrix of class "dfmSparse"
##
                  features

```

Compression: sparse matrix format

used because many forms of matrix are very sparse - for example, document-term matrixes

```
# how many cell counts are zeros
sum(myDfm==0) / (ndoc(myDfm) * nfeature(myDfm)) * 100

## [1] 91.67571

object.size(myDfm)

## 1123544 bytes

object.size(as.matrix(myDfm))

## 4762040 bytes
```

Additional course preview

Day	Date	Topic(s)	Details
Mon	17 Aug	Course overview and introduction to data science	We will use this session to get to know the range of interests and experience students bring to the class, as well as to survey the approaches to be covered. We will also discuss and demonstrate the R software.
Tue	18 Aug	Research design issues in data science	Sampling, causal inference from observational data, dif- ferences with experimental settings, features. variables. Basic probability and statistics, binomial and Normal dis- tributions. Cross-validation, predictive accuracy versus marginal effects. Model selection.
Wed	19 Aug	Linear Regression	The basic linear regression model, with a focus on prediction.
Thu	20 Aug	Generalized linear regression	Logistic regression, GAMs.
Fri	21 Aug	Resampling methods	Cross-validation, bootstrap.

Additional course preview

Mon	24 Aug	Association rules and clustering	Cluster analysis, k-means clustering, and hierarchical clustering
Tue	25 Aug	Machine Learning	Decision trees, k-Nearest Neighbour, Naive Bayes. Evaluation metrics, precision and recall, cross-validation.
Wed	26 Aug	Unsupervised learning and dimensional reduction.	Principal components analysis, correspondence analysis.
Thu	27 Aug	Text analysis	Working with text in R, sentiment analysis, dictionary methods.
Fri	28 Aug	Mining the Social Web	Working with the Twitter API, Facebook API, JSON data, and examples.
